

# Introduction to Algorithms

## Chapter 23 : Minimum Spanning Trees

Xiang-Yang Li and Haisheng Tan

School of Computer Science and Technology  
University of Science and Technology of China (USTC)

Fall Semester 2023

# Outline of Topics

## 23.1 Growing a minimum spanning tree

Greedy Method for MST

Recognize safe edges

## 23.2 The algorithms of Kruskal and Prim

Kruskals algorithm

Prims algorithm

# Basic definitions and properties

In this chapter, we shall examine two algorithms for solving the minimum spanning-tree problem: **Kruskals algorithm** and **Prims algorithm**.

- ▶ Section 23.1 introduces a generic minimum-spanning-tree method that grows a spanning tree by adding one edge at a time.
- ▶ Section 23.2 gives two algorithms that implement the generic method.

# Basic definitions and properties

## Definition 1:

Given a connected, undirected graph  $G = (V, E)$ , for each edge  $(u, v) \in E$ , having a weight  $w(u, v)$ .

We wish to find an acyclic subset  $T \subseteq E$  that connects all of the vertices and whose total weight is minimized.

$$w(T) = \sum_{(u,v) \in T} w(u, v)$$

Since  $T$  is acyclic and connects all of the vertices, it must form a tree, which we call a spanning tree since it spans the graph  $G$ . We call the problem of determining the tree  $T$  the minimum-spanning-tree problem(MST).

## Example of a connected graph and MST

# Greedy Method for MST

The two algorithms (Kruskals Algorithm and Prim's Algorithm) we consider in this chapter run in time  $O(|E|\log|V|)$  using a **greedy approach** to the problem.

## **Greedy strategy:**

Grows the minimum spanning tree one edge at a time and manages a set of edges  $A$ , maintaining the following loop invariant:

**Prior to each iteration,  $A$  is a subset of some minimum spanning tree.**

# Generic MST Algorithm

At each step we determine an edge  $(u, v)$  such that  $A \cup (u, v)$  is still a subset of a MST and  $(u, v)$  is called a **safe edge** for  $A$ .

GENERIC-MST( $G, w$ )

- 1:  $A = \emptyset$
- 2: **while**  $A$  does not form a spanning tree **do**
- 3:     **find an edge**  $(u, v)$  **that is safe for**  $A$
- 4:      $A = A \cup (u, v)$
- 5: **return**  $A$

# Cut and Light Edge

## Definition 2:

- ▶ A **cut**  $(S, V - S)$  of an undirected graph  $G = (V, E)$  is a partition of  $V$ .
- ▶ An edge  $(u, v) \in E$  crosses the cut iff one of its endpoints is in  $S$  and the other is in  $V - S$
- ▶ An edge is a **light edge** crossing a cut if its weight is the minimum of any edge crossing the cut
- ▶ We call a cut **respects** a set  $A$  of edges if no edge in  $A$  crosses the cut.

# Example of Cut and Light Edge

# Recognize safe edges

## Theorem 23.1:

Let  $G = (V, E)$  be a connected, undirected graph with a real-valued weight function  $w$  defined on  $E$ . Let  $A$  be a subset of  $E$  that is included in some minimum spanning tree for  $G$ , let  $(S, V - S)$  be any cut of  $G$  that **respects**  $A$ , and let  $(u, v)$  be a **light edge crossing**  $(S, V - S)$ .

Then, edge  $(u, v)$  is **safe** for  $A$ .

# Recognize safe edges

# Recognize safe edges

## Proof:

Suppose that  $T$  is an MST containing  $A$  but not the light edge  $(u, v)$ , then there is at least one edge on the path  $p$  that crosses the cut, say  $(x, y)$ .

## 1. form a new spanning tree $T'$ :

Then  $(x, y)$  is not in  $A$ . Because  $p$  is the unique path from  $u$  to  $v$  in  $T$ , so removing  $(x, y)$  breaks  $T$  into two components. Adding  $(u, v)$  reconnects them to form a new spanning tree  $T' = T - \{(x, y) \cup (u, v)\}$ .

# Recognize safe edges

## 2. show that $T'$ is MST:

Since  $(u, v)$  is a light edge crossing  $(S, V - S)$  and  $(x, y)$  also crosses this cut,  $w(u, v) \leq w(x, y)$ . Therefore,

$$\begin{aligned} w(T') &= w(T) - w(x, y) + w(u, v) \\ &\leq w(T) \end{aligned}$$

But  $T$  is a minimum spanning tree, so that  $w(T) \leq w(T')$ . thus  $T'$  must be a minimum spanning tree also.

## 3. show that $(u, v)$ is a safe edge for $A$ :

We have  $A \subseteq T'$ , since  $A \subseteq T$  and  $(x, y) \notin A$ , thus  $A \cup \{(u, v)\} \subseteq T'$ . Since  $T'$  is a MST,  $(u, v)$  is safe for  $A$ .

# Corollary to Theorem 23.1

## Corollary to theorem 23.1:

Let  $G = (V, E)$  be a connected, undirected graph with a real-valued weight function  $w$  defined on  $E$ . Let  $A$  be a subset of  $E$  that is included in some minimum spanning tree for  $G$ , and let  $C = (V_c, E_c)$  be a connected component (tree) in the forest  $G_A = (V, A)$ .

If  $(u, v)$  is a light edge connecting  $C$  to some other component in  $G_A$ , then  $(u, v)$  is safe for  $A$ .

### Proof:

Since the cut  $(V_c, V - V_c)$  respects  $A$ , and  $(u, v)$  is a light edge for this cut,  $(u, v)$  is safe for  $A$ .

# Kruskal and Prim Algorithms

- ▶ In **Kruskals algorithm**, the set  $A$  forms a **forest**. The safe edge added to  $A$  is always a least-weight edge in the graph that connects two distinct components
- ▶ In **Prims algorithm**, the set  $A$  forms a **single tree**. The safe edge added to  $A$  is always a least-weight edge connecting the tree to a vertex not in the tree.

# Kruskals algorithm

**Kruskals algorithm** finds a safe edge to add to the growing forest by finding, of all the edges that connect any two trees in the forest, an edge  $(u, v)$  of **the least weight**.

Let  $C_1$  and  $C_2$  denote the two trees that are connected by  $(u, v)$ . Since  $(u, v)$  is a light edge, connecting  $C_1$  to some other tree,  $(u, v)$  is a safe edge for  $C_1$ . (Corollary 23.2)

Simply speaking, at each step Kruskals algorithm adds to the forest an edge of the least possible weight (greedy).

# Kruskals algorithm

MST-KRUSKAL( $G, w$ )

- 1:  $A = \emptyset$
- 2: **for** each vertex  $v \in G.V$  **do**
- 3:     MAKE-SET( $v$ )
- 4: sort the edges of  $G.E$  into nondecreasing order by weight  $w$
- 5: **for** each edge  $(u, v) \in G.E$ , taking in nondecreasing order by weight  $w$ , **do**
- 6:     **if** FIND-SET( $u$ )  $\neq$  FIND-SET( $v$ ) **then**
- 7:          $A = A \cup \{(u, v)\}$
- 8:         UNION( $u, v$ )
- 9: **return**  $A$

   *//  $O(E \log E)$*
- 5: **for** each edge  $(u, v) \in G.E$ , taking in nondecreasing order by weight  $w$ , **do**
- 6:     **if** FIND-SET( $u$ )  $\neq$  FIND-SET( $v$ ) **then**
- 7:          $A = A \cup \{(u, v)\}$
- 8:         UNION( $u, v$ )     *//totally  $O(E)$  FIND-SET and UNION*
- 9: **return**  $A$

# Kruskals Algorithm Complexity

## Complexity:

Assume that we use the disjoint-set-forest implementation with the union-by-rank and path-compression heuristics

Initializing the set A in line 1 takes  $O(1)$  time

Sort the edges in line 4 is  $O(E \lg E)$  time

The for loop of lines 5-8 performs  $O(E)$  FIND-SET and UNION operations on the disjoint-set forest

Along with the  $|V|$  MAKE-SET operations, these take a total of  $O((V + E)\alpha(V))$  time

Since  $\alpha(|V|) = O(\lg V) = O(\lg E)$ , the running time is  $O(E \lg E)$

Since  $|E| < |V|^2$ ,  $\lg |E| = O(\lg V)$ , the running time is  $O(E \lg V)$

# Prims algorithm

**Prims algorithm** operates much like Dijkstras algorithm for finding shortest paths in a graph.

Prims algorithm has the property that the edges in the set A **always form a single tree**.

Each step adds to the tree A a light edge that connects A to an isolated vertex – one on which no edge of A is incident.

Simply speaking, **at each step it adds to the tree an edge that contributes the minimum amount possible to the trees weight (greedy).**

# Prims algorithm

MST-PRIM( $G, w, r$ )

```

1: for each vertex  $u \in G, V$  do
2:    $u.key = \infty$ ;      //  $u.key$  stores the minimum weight of any
   edge connecting  $v$  to a vertex in the current tree
3:    $u.\pi = NIL$ 
4:  $r.key = 0$ 
5:  $Q = G.V$       //  $Q$  contains nodes not yet joining the tree
6: while  $Q \neq \emptyset$  do
7:    $u = \text{EXTRACT-MIN}(Q)$       // adding  $(u.\pi, u)$  to the tree
8:   for each  $v \in G.Adj[u]$  do
9:     if  $v \in Q$  and  $w(u, v) < v.key$  then      // updating keys
10:       $v.\pi = u$ 
11:       $v.key = w(u, v)$ 

```

# Prims algorithm

MST-PRIM( $G, w, r$ )

```

1: for each vertex  $u \in G, V$  do
2:    $u.key = \infty$ 
3:    $u.\pi = NIL$ 
4:  $r.key = 0$ 
5:  $Q = G.V$            //BUILD-MIN-HEAP,  $O(V)$ 
6: while  $Q \neq \emptyset$  do           //V loops
7:    $u = \text{EXTRACT-MIN}(Q)$            // $O(\log V)$  for each loop
8:   for each  $v \in G.Adj[u]$  do //           //2E loops totally
9:     if  $v \in Q$  and  $w(u, v) < v.key$  then
10:       $v.\pi = u$ 
11:       $v.key = w(u, v)$            //DECREASE-KEY

```

# Prims algorithm Complexity

## Complexity:

*Implement the min-priority queue  $Q$  as a binary min-heap:*

Lines 1 - 5 : use the BUILD-MIN-HEAP to perform  $O(V)$

The body of the while loop executes  $|V|$  times, since each EXTRACT-MIN operation takes  $O(\lg V)$  time, the total time is  $O(V \lg V)$  time. The for loop in lines 8 - 11 executes  $O(E)$  times altogether, since the sum of the lengths of all adjacency lists is  $2|E|$ .

Line 11 involves an implicit DECREASE-KEY operation on the min-heap, which a binary min-heap supports in  $O(\lg V)$  time.

Total time:  $O(V \lg V + E \lg V) = O(E \lg V)$

*What about implementing the min-priority queue  $Q$  as a FIB-Heap?*
